

## ASSIGNMENT- 07.5

**Name:** Rishitha Kunchala

**HT.No:** 2303A51333

**Batch:** 20

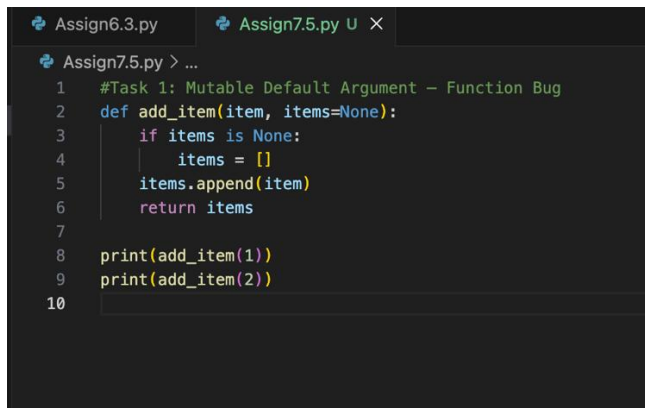

### Task 1: Mutable Default Argument – Function Bug

The given function uses a mutable default argument, which causes data to persist across function calls and leads to unexpected behavior

```
# Bug: Mutable default argument
def add_item(item, items=[]):
    items.append(item)
    return items
print(add_item(1))
print(add_item(2))
```

**.Prompt: #Fix the Python function where a mutable default argument causes unexpected behavior.**

**Code:**

A screenshot of a code editor with two tabs: 'Assign6.3.py' and 'Assign7.5.py'. The 'Assign7.5.py' tab is active, showing the following Python code:

```
1 #Task 1: Mutable Default Argument – Function Bug
2 def add_item(item, items=None):
3     if items is None:
4         items = []
5     items.append(item)
6     return items
7
8 print(add_item(1))
9 print(add_item(2))
10
```

**Result:**

A screenshot of a terminal window with a dark background. It shows the file path 'op/AI-Assisted-Coding/Assign7.5.py' followed by the output of the program:

```
[1]
[2]
```

**Observation:**

The AI correctly identified that mutable default arguments are shared across function calls. Replacing the default list with `None` and initializing it inside the function prevents unintended data sharing and ensures correct behavior.

**Task 2:** Task 2: Floating-Point Precision Error

Direct comparison of floating-point numbers leads to incorrect results due to precision limitations.

```
# Bug: Floating point precision issue
def check_sum():
    return (0.1 + 0.2) == 0.3
print(check_sum())
```

**Prompt:** #Fix the floating-point comparison issue  
using tolerance

**Code:**

```
#Task 2: Floating-Point Precision Error
def check_sum():
    return abs((0.1 + 0.2) - 0.3) < 1e-9

print(check_sum())
```

**Result:**

True

**Observation:**

The AI correctly addressed floating-point precision issues by using a tolerance-based comparison instead of direct equality, which is a recommended and reliable approach in numerical computing.

**Task 3:** Task 3: Recursion Error – Missing Base Case. The recursive function lacks a base case, resulting in infinite recursion.

**Prompt:** # Fix the recursion error caused by a missing base case.

# Bug: No base case

```
def countdown(n):
```

```
    print(n)
```

```
    return countdown(n-1)
```

```
countdown(5)
```

**Code:**

```
#Task 3: Recursion Error – Missing Base Case
def countdown(n):
    if n < 0:
        return
    print(n)
    countdown(n - 1)

countdown(5)
```

**Result:**

```
5
4
3
2
1
0
```

**Observation:**

The AI correctly identified the absence of a base condition and added a stopping condition, preventing infinite recursion and ensuring safe execution.

**Task 4:** Task 4: Dictionary Key Error. Accessing a non-existent key in a dictionary causes a

runtime `KeyError`.

# Bug: Accessing non-existing key

```
def get_value():  
    data = {"a": 1, "b": 2}  
    return data["c"]  
print(get_value())
```

**Prompt:** #Fix the dictionary `KeyError` using safe access methods..

**Code:**

```
#Task 4: Dictionary Key Error  
def get_value():  
    data = {"a": 1, "b": 2}  
    return data.get("c", "Key not found")  
  
print(get_value())
```

**Result:**

```
Key not found
```

## Observation

The AI resolved the issue by using the `.get()` method, which safely handles missing keys and prevents runtime errors.

**Task 5:** Task 5: Infinite Loop – Wrong Condition. The loop never terminates because the loop variable is not updated.

# Bug: Infinite loop

```
def loop_example():  
    i = 0  
    while i < 5:  
        print(i)
```

**Prompt: #Fix the infinite loop by correcting the loop condition.**

**Code:**

```
#Task 5: Infinite Loop - Wrong Condition  
def loop_example():  
    i = 0  
    while i < 5:  
        print(i)  
        i += 1  
  
loop_example()
```

**Result:**

```
0  
1  
2  
3  
4
```

**Observation:**

The AI correctly identified the missing increment statement and fixed the infinite loop by updating the loop variable inside the loop

### **Task 6:** Task 6: Unpacking Error – Wrong Variables

Tuple unpacking fails because the number of variables does not match the tuple size

# Bug: Wrong unpacking

a, b = (1, 2, 3)

**Prompt: # Fix the tuple unpacking error caused by mismatched variables.**

**Code:**

```
#Task 6: Unpacking Error – Wrong Variables
a, b, _ = (1, 2, 3)
print(a, b)
```

**Result:**

```
1 2
```

**Observation:**

The AI fixed the unpacking issue by using an underscore (\_) to ignore extra values, which is a Pythonic and safe practice

**Task 7:** Task 7: Mixed Indentation – Tabs vs Spaces. Inconsistent indentation causes syntax or runtime errors in Python.

# Bug: Mixed indentation

```
def func():
```

```
    x = 5
```

```
    y = 10
```

```
    return x+y
```

**Prompt:** # Fix the Python code with mixed indentation.

**Code:**

```
#Task 7: Mixed Indentation – Tabs vs Spaces
def func():
    x = 5
    y = 10
    return x + y

print(func())
```

**Result:**

```
15
```

**Observation:**

The AI resolved the issue by applying consistent indentation using spaces, which is the recommended Python coding standard.

**Task 8:** Task 8: Import Error – Wrong Module Usage. The code attempts to import a non-existent module, causing an import error.

**Prompt:** # Fix the incorrect module import in the Python code.

# Bug: Wrong import

```
import maths
```

```
print(maths.sqrt(16))
```

**Code:**

```
#Task 8: Import Error – Wrong Module Usage
import math
print(math.sqrt(16))
|
```

**Result:**

```
4.0
```

**Observation:**

The AI correctly identified the incorrect module name and replaced it with the standard `math` module, resolving the import error.
